# Distance ?

---

This is the distance used to compute the price of a taxi ride

---

Actual distance between the starting end ending points of your journey

# Distance ?

## Distance measures

- ▶ Euclidean distance

$$S(x, y) = \sqrt{\sum_{i=1}^n (x_i - y_i)^2}$$

- ▶ Manhattan distance also referred as city block distance or taxicab distance

$$S(x, y) = \sum_{i=1}^n |x_i - y_i|$$

Let us suppose that (2, 3) are the coordinates of the starting point and (11,14) are the coordinates of the destination. Then Euclidian distance between the starting point and destination is: 14.21. At the same time Manhattan distance is 20.

## Similarity or Distance

Problem statement: *Given two objects  $\mathcal{O}_1$  and  $\mathcal{O}_2$ , determine a value of the similarity between two objects*

# Metric (some times referred as distance function)

## Definition

A function  $d : X \times X \rightarrow \mathbb{R}$  is called metric if for any elements  $x, y$  and  $z$  of  $X$  the following conditions are satisfied.

1. Non-negativity or separation axiom

$$S(x, y) \geq 0$$

2. Identity of indiscernibles, or coincidence axiom

$$S(x, y) = 0 \Leftrightarrow x = y$$

3. Symmetry

$$S(x, y) = S(y, x)$$

4. Subadditivity or triangle inequality

$$S(x, z) \leq S(x, y) + S(y, z)$$

# Examples 1

- ▶ Euclidean distance

$$S(x, y) = \sqrt{\sum_{i=1}^n (x_i - y_i)^2}$$

- ▶ Manhattan distance also referred as city block distance or taxicab distance

$$S(x, y) = \sum_{i=1}^n |x_i - y_i|$$

- ▶ Chebyshev distance

$$S(x, y) = \lim_{k \rightarrow \infty} \left( \sum_{i=1}^n |x_i - y_i|^k \right)^{\frac{1}{k}} = \max_i (|x_i - y_i|)$$

## Examples 2

- ▶ Mahalanobis distance

$$S(x, y) = \sqrt{(x - y)^T C^{-1} (x - y)}$$

where  $C$  is the covariance matrix. Takes into account impact of data distribution.

- ▶ Cosine distance Cosine similarity is the measure of the angle between two vectors

$$S_c(x, y) = \frac{x \cdot y}{\|x\| \|y\|}$$

Usually used in high dimensional positive spaces, ranges from  $-1$  to  $1$ . Cosine distance is defined as follows

$$S_C(x, y) = 1 - S_c(x, y)$$

## Examples 3: Distances between strings

- ▶ Levenshtein or SED distance. SED - minimal number of single-character edits required to change one string into another. Edit operations are as follows:
  - ▶ insertions
  - ▶ deletions
  - ▶ substitutions
- ▶  $SED(\text{delta}, \text{delata})=1$  delete "a" or  $SED(\text{kitten}, \text{sitting})=3$  : substitute "k" with "s", substitute "e" with "i", insert "g".
- ▶ Hamming distance Similar to Levenshtein but with substitution operation only. Frequently used with categorical and binary data.

## $k$ -nearest neighbour ( $k$ -NN) classification

- ▶ Let  $N$  be a labeled set of points belonging to  $c$  different classes such that

$$\sum_{i=1}^c N_i = N$$

- ▶ Classification of a given point  $x$ 
  - ▶ Find  $k$  - nearest points to the point  $x$ .
  - ▶ Assign  $x$  the majority label of neighbouring ( $k$ -nearest) points

## $L_p$ norms

- ▶ The real valued function  $f$  defined in a vector space  $V$  over the subfield  $F$  is called a norm if for any  $a \in F$  and all  $u, v \in V$  it satisfies following three conditions
  - ▶  $f(av) = |a| f(v)$
  - ▶  $f(u + v) \leq f(u) + f(v)$
  - ▶  $f(v) = 0 \Rightarrow v = 0$
- ▶  $L_p$  is defined as follows

$$S(\bar{X}\bar{Y}) = \left( \sum_{i=1}^d |x_i - y_i|^p \right)^{\frac{1}{p}}$$

- ▶ In case of  $p = 1$  we are dealing with already known to you Manhattan distance. In case of  $p = 2$  Euclidean.

## Impact of Domain-Specific Relevance

There are cases when some features are more important than the others. Generalized  $L_p$  distance is most suitable in such cases.

$$S(x, y) = \left( \sum_{i=1}^d a_i |x_i - y_i|^p \right)^{1/p}$$

This distance is frequently referred as *Minkowski distance*

## Impact of High Dimensionality (Curse of Dimensionality)

*Curse of dimensionality* - term introduced by Richard Bellman. Referred to the phenomenon of efficiency loss by distance based data-mining methods. Let us consider the following example.

- ▶ Consider the unit cube in  $d$  - dimensional space, with one corner at the origin.
- ▶ What is the Manhattan distance from the arbitrary chosen point inside the cube to the origin?

$$S(\bar{0}, \bar{Y}) = \sum_{i=1}^d (Y_i - 0)$$

Note that  $Y_i$  is random variable in  $[0, 1]$

- ▶ The result is random variable with a mean  $\mu = d/2$  and standard deviation  $\sigma = \sqrt{d/12}$
- ▶ The ratio of the variation in the distances to the mean value is referred as *contrast*

$$G(d) = \frac{S_{max} - S_{min}}{\mu} = \sqrt{\frac{12}{d}}$$
